

Error Handling - Test for Task Error

Summary: We've created a sample integration that creates a mapping error, so that we can show how to test for an Error after any task. The mapping condition will try to retrieve the third element of a string array, and the default test input only has 2 elements. This will cause an error. By creating a local variable called ErrorMessage, we can then use the Edge conditions to test to see if the ErrorMessage exists (has data in it from the Error), or whether it remains empty (success).

How to use the Sample Integration

The Error Handline sample [here in GitHub](#) is an example of how this is done.

- Download the sample .json file to your local computer with a browser
- Create a new integration (you can call it ErrorHandlerSample or whatever you want)
- Use the Upload button on the main ribbon at the top of the canvas to import the sample .json file. Select "Upload".
- Select the sample .json file from your local drive, and click on Open.
- Fill out your email address in the two "Send Email" tasks to test it.

To TEST: The Default input variable will cause it to have an error and follow that route. Just click on **TEST** button at the top right of your screen, and then click on [TEST INTEGRATION](#).

Test Integration

API API Trigger 📄 Version 7

Please provide values to the following variables:

Input Variable	Value
[s] string_array	<div><div>1 ✕</div><div>2 ✕</div><div>Add a string value</div></div>

CLOSE TEST INTEGRATION

Test again with a successful mapping task:

If you add a digit by typing 3 (or choose any number) to the test input, it will go to the success route.

Test Integration

API API Trigger 📄 Version 7

Please provide values to the following variables:

Input Variable	Value
[s] string_array	<div><div>1 ✕</div><div>2 ✕</div><div>3</div></div>

CLOSE TEST INTEGRATION

You should receive an email with an indication of Success, and it will include the third element in the email body.

How to Configure from Scratch

Here are the instructions for how to replicate this sample.

1. For the task that you want to test for the error, set the Retry on Failure setting to "Ignore" for the "When integration is run synchronously".
 - a. This tells Integration to continue running even if there was an error. Otherwise, it will halt execution and put the integration into a Failure state.

Mapping

Data mappings can be used to assign new values to variables, get and set properties of JSON objects, and apply transform functions to values. [Read more.](#)

Input		Output
 string_array .GET("2")	→	 output_str

Open the Data Mapping Editor to view default values and error throwing settings.

 Open Data Mapping Editor

Retry on Failure

When integration is run synchronously...

Ignore

When integration is run asynchronously...

None

2. Create a variable in your integration called "ErrorMessage" and leave the definition and default value empty

Configure Variable

Name

ErrorMessage

Data Type

STR

String

Default Value

Blank default value means...

☐ Null

☒ Empty String

i

An 'input' variable allows integration runners to pass values in. 'Output' variables are returned to integration runners.

☐ Use as an input to integration

☐ Use as an output of integration

Searchable in Execution Logs

No

(Note: If you don't create the variable, the edge condition will not work)

3. On the error edge, add a condition (click on the line between your tasks), you can check for this condition to see if there is an error: `exists($ErrorMessage$)`

```

graph TD
    A[API Trigger] --> B[Data Mapping ID:2]
    B -- Error --> C[Send Email ID:1]
    B -- Success --> D[Send Email 1 ID:3]
  
```

Edge
